FOREWORD

This is the third volume of a series of catalogs published by the National Aeronautics and Space Administration to document data acquired from the Nimbus 4 Meteorological Satellite. This volume covers the period from 1 July through 31 August 1970 with subsequent catalogs to contain documentation for succeeding periods throughout the useful lifetime of Nimbus 4.

Background information concerning the Nimbus 4 Meteorological Satellite system and a description of the experiments and data formats have been published separately in the Nimbus IV User's Guide, with post-launch User's Guide information changes and corrections included in the data catalogs. The Nimbus 4 catalogs present the type of data available, anomalies in the data, if any, and geographic location and time of the data.

The assembly and editing of this catalog was accomplished by the Geophysics and Aerospace Division of Allied Research Associates, Inc. (ARA), Concord, Massachusetts under contract number NAS 5-10343 with the Goddard Space Flight Center, NASA, Greenbelt, Maryland.

SECTION 1

SUMMARY OF OPERATIONS

1.1 Introduction

Nimbus 4 was successfully launched from the Western Test Range at Vandenburg AFB, California, into a near circular orbit (587 X 593 n. mi.) at 08hr 17m 57sec Universal Time on 8 April 1970.

This third volume of the Nimbus 4 data catalog reflects complete documentation for the period 1 July 1970 through 31 August 1970, orbits 1124 to 1956.

The sensory data output and total operating time from launch (8 April 1970) through orbit 1956 on 31 August 1970 were as follows:

IDCS	24,568 Frames (Pictures)
THIR (11.5 μ m)	3136 Hours
THIR (6.7 μ m)	1825 Hours
SIRS	3133 Hours
FWS	1316 Hours (total to failure, orbit 815)
SCR	3133 Hours
MUSE	3143 Hours
IRIS	3114 Hours
BUV	3076 Hours
IRLS	7330 Frames (Data)

The Filter Wedge Spectrometer (FWS) experiment failed during orbit 815, 8 June 1970 and no further data have been received from the experiment.

Gridding of the Nimbus 4 pictorial data (IDCS and THIR) is generally accurate to within ± 1 degree of great circle arc (± 60 n. miles) at the satellite subpoint. Mean satellite attitude errors have been less than 0.5 degree of nadir.

Data from the High Data Rate Storage Subsystem (HDRSS) B has been excellent. However, a flutter in the HDRSS A, at approximately 100 Hz, has affected both the analog and digital THIR, and IDCS data. This flutter was first observed around orbit 450 and has continued to increase.

Quality of sensory data varies from satisfactory to excellent. The following subsections 1.2 to 1.11 summarize the operational highlights of the individual experiments and call attention to known data anomalies in this catalog period.

The user is referred to the Nimbus IV User's Guide for a complete description of the Nimbus 4 experiments.

1.2 The Image Dissector Camera System (IDCS) Experiment

The Image Dissector Camera System performance has been satisfactory. Pictures from HDRSS B are of good quality (see Figure 1-1 of Volume 1). HDRSS A video playbacks, with 100 Hz flutter interferences, have a somewhat reduced image quality (see Figure 1-1a of Volume 2). The Sensors "On" Table in Section 2 shows the IDCS data orbits produced from HDRSS A playbacks.

The resolution of the IDCS (2 to 3 n. miles at the subsatellite point) and the system transfer function which tends to favor tonal rendition near the white end of the gray scale, are well suited for the IDCS intended purpose of cloud mapping.

1.3 The Temperature-Humidity Infrared Radiometer (THIR) Experiment

The quality of the THIR data recorded on HDRSS B from the water vapor channel ($6.7 \mu\text{m}$) and the window channel ($11.5 \mu\text{m}$) has been excellent.

The quality of the HDRSS A THIR data deteriorated after orbit 450, 11 May 1970 because of increased noise caused by a flutter in this HDRSS tape recorder. Because of this, the Root Mean Square (RMS) THIR temperature variations increased (see Figure 1-1) making digitization of THIR data from HDRSS A essentially meaningless after orbit 2000. HDRSS A THIR data collected between orbits 1000 and 2000 cannot be reduced to NMRT format until a suitable filter program for these higher noise levels is devised. (THIR imagery from HDRSS A has been processed for this catalog period and is available if the user desires this product.) The Sensors "On" Table in Section 2 lists the data produced from HDRSS A playbacks. Figure 1-1b of Volume 2 is an example of a noise degraded THIR $11.5 \mu\text{m}$ picture produced from a HDRSS A playback.

When noise is relatively low (as was the case of HDRSS B data and early HDRSS A data) it is possible to attenuate the periodic noise frequencies by filtering without seriously degrading the data. This is done upon request of the user whenever radiation maps are produced by the National Space Science Data Center. There are two basic steps involved in filtering the data. First, a Fourier analysis of sample data from the backscan housing is done to establish the "noise" frequencies present and their magnitudes. The filter program is designed to reduce these specific frequencies. Next, the digitized data are passed through the program and a filtered data tape is generated. Radiation maps are then produced from this filtered data tape.

Variations in film density can and do occur in the photographic product. The montage in Figure 1-2 of Volume 2 illustrates the orbit to orbit density variations that can occur in one day of THIR data. These variations have been attenuated photographically in the montage presentation of Section 4 by controlling the exposure time as a function of film density (dodging). Figure 1-3 of Volume 2 shows the same montage of Figure 1-2 made from dodged photographs. The dodging process brings out the details in the clouds and surfaces and makes the prints better suited for qualitative and first look analyses.

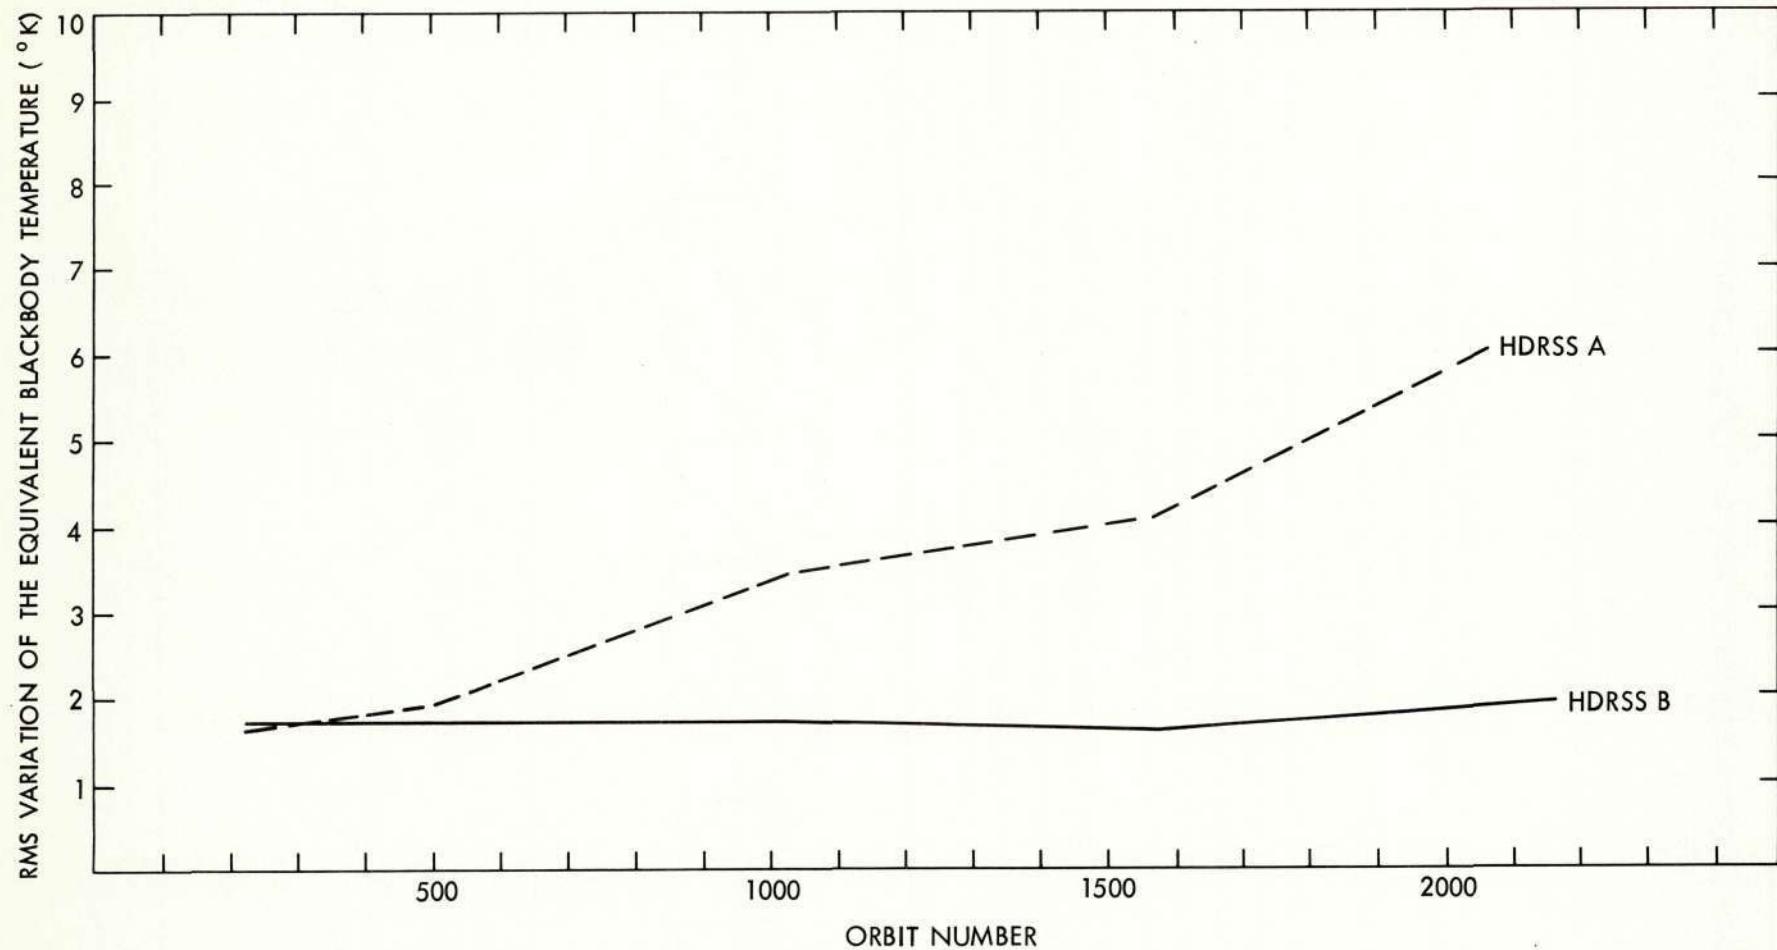

Figure 1-1. Root Mean Square (RMS) Variation of the Equivalent Blackbody Temperature in the Range 270 - 290°K from Nimbus 4 THIR 11.5 μ m Channel

Because of film density variations no accurate quantitative analyses of the temperature or radiation can be made from the film or print.

The film archived at the National Space Science Data Center (NSSDC) has been reproduced undodged (no exposure control). If dodged data are desired they must be specifically requested.

The bolometer, housing and electronic temperatures were maintained at about 19° C, 19° C and 23° C respectively throughout this catalog period.

1.4 The Infrared Interferometer Spectrometer (IRIS) Experiment*

During this period the Image Motion Compensation (IMCC) scan in the earth scan has decreased in amplitude to 3.85 degrees and has become non-linear (Figure 1-2). Since the period of earth scan remains at 13.1 seconds the degradation in amplitude and linearity is attributed to increased friction in the IMCC torque motor. There is no discernable loss of quality in the atmospheric spectra collected.

Optics and optics housing temperature remain essentially unchanged this reporting period. The neon reference signal was 2.3 volts at the beginning of July and 2.1 volts at the end of August. Responsivity and noise equivalent radiance (NER) (Figure 1-3) have remained essentially at the same level since launch.

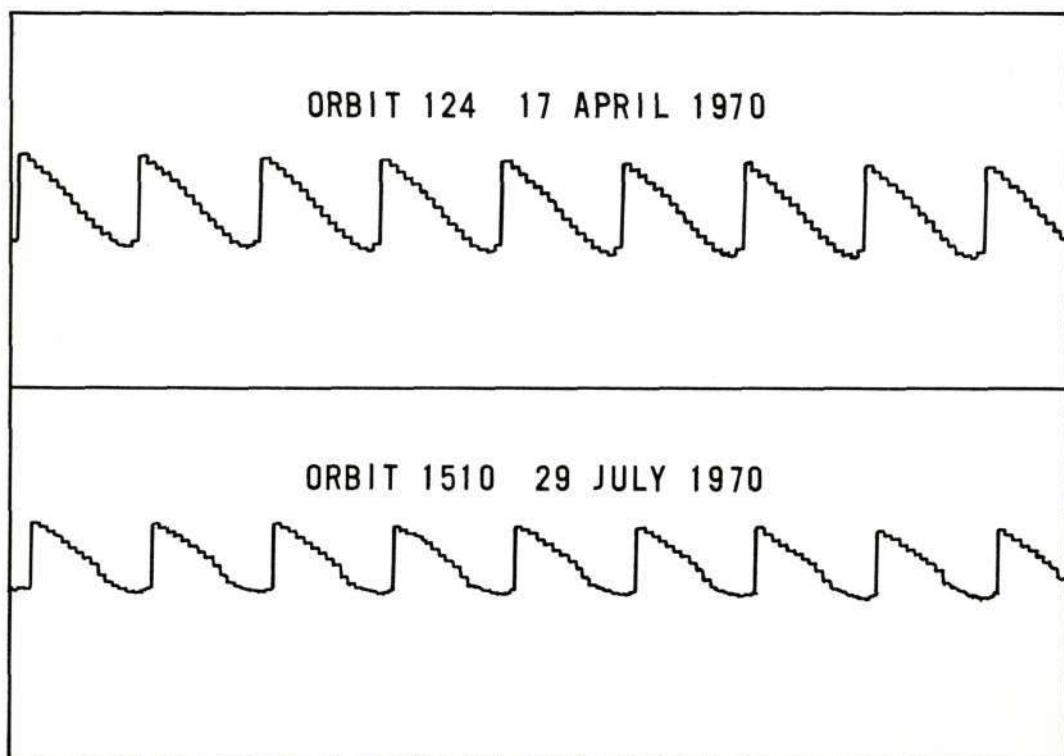

Figure 1-2. IRIS Image Motion Compensation (IMCC) Angular Scan Voltage Changes between April and July 1970

*Contributed by R. Hanel, B. Schlachman and M. Sing of NASA/GSFC.

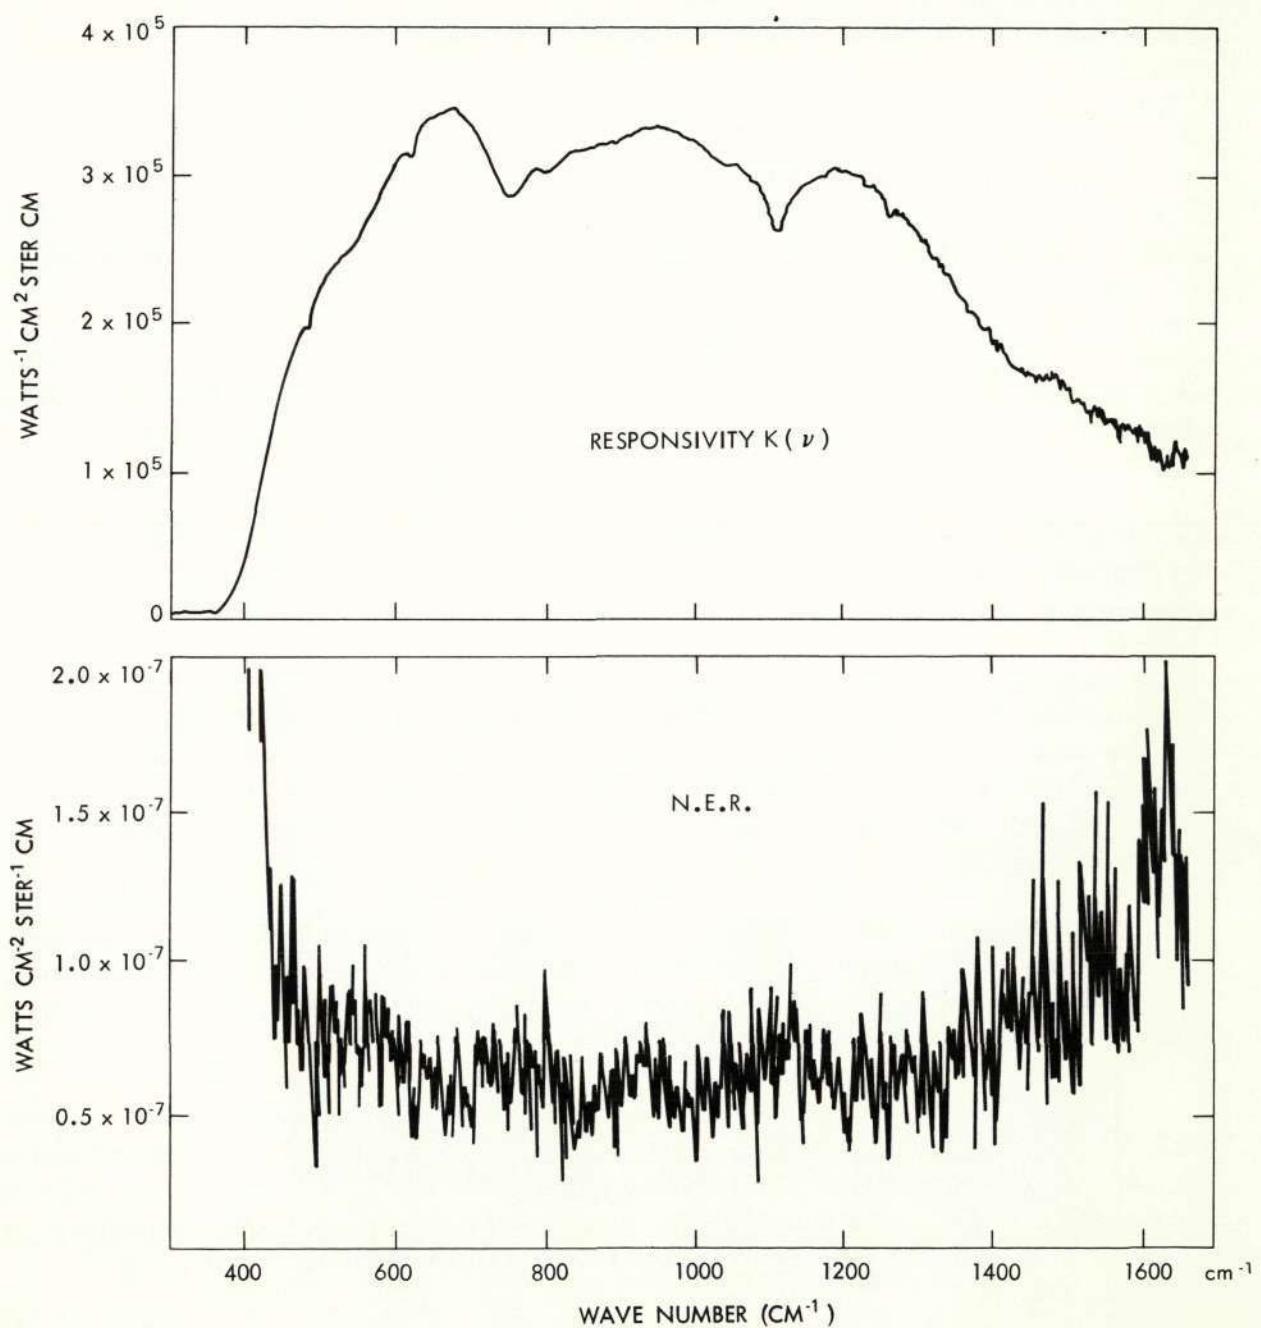

Figure 1-3. IRIS Responsivity and Noise Equivalent Radiance (N.E.R.)
for Orbit 1509, July 30, 1970

Responsivity and N.E.R. ordinate values in figures 1-6 and 1-7 of Volume 1 are incorrect. These values are corrected by the superposition of the ordinate values from figure 1-3 of this volume.

1.5 The Satellite Infrared Spectrometer (SIRS) Experiment*

1.5.1 Instrument Performance

During the period covered by this catalog the performance of some of the SIRS-B channels degraded. Channel 1 output quite frequently was at a constant level of 1023 (full scale) bits. The radiance level of any channel was set at zero whenever its output exceeded 1000 bits; users may easily exclude these data by testing every datum for zero. The first calibration showing an instability in the channel 1 gain occurred during orbit 1736. Infrequently thereafter the gain of channel 1 would be low. The use of the channel 1 data is discouraged after orbit 1736 unless precautions are taken to identify the data recorded when that channel was malfunctioning.

Channel 4 underwent a sudden 10% increase in gain that was first detected in the calibration event during orbit 1592. The last calibration event recorded prior to the gain change was during orbit 1588. Channel 4 calibration between these two orbits is not known.

Occasionally channel 9 output was reduced to a near-zero level. The radiances for channel 9 are set to zero for these periods. During calibration of orbit 1780 the output of channel 9 was less than it had been previously and continued to be erratic through the period covered by this catalog. The data from this channel should not be used after orbit 1780 without taking considerable precautions to eliminate erroneous data.

Channel 12 continued to perform erratically. These data also must be subjected to elaborate screening to identify the limited amount of usable measurements. Channel 14 also continued to perform in an unsatisfactory manner characterized by a wandering level of sensitivity.

An adjustment to the calibration constants used to compute the radiances was made at orbit 1591. These changes adjusted for the 10% changes in gain of channel 4, for minor drifts in the gains of channels 5 and 11, and for a 4% increase in the channel 14 gain due to drift. Also minor corrections to the space-viewed level were made in channels 3, 5, 8 and 11 which correspond to adjustments of less than 0.2 erg.
[cm² sec strd cm⁻¹]⁻¹.

1.5.2 Data Utilization

A complete set of SIRS-A (Nimbus 3 SIRS experiment) data tapes containing radiance values through Orbit 5787, 19 June 1970, has been sent to the National

*Contributed by J. Lienesch of NESS/NOAA

Space Science Data Center at Goddard. It is expected that the initial copies of the SIRS-B (Nimbus 4 SIRS experiment) data tapes will be available within a few months. The format of these tapes will be more compact than the SIRS-A data tapes, thus enabling the user to obtain a greater amount of experimental data on each data tape.

1.6 The Monitor of Ultraviolet Solar Energy (MUSE) Experiment

The MUSE experiment has performed satisfactorily in both manual and automatic modes during this catalog period. The functional telemetry monitors have indicated a steady and stable electrometer operation. There has been no indication of electrometer drift.

The ultraviolet sensors outputs continued to follow the same trends that had been shown during the second catalog period. Sensors 1, 2, and 3 (2600\AA , 1216\AA , and 1800\AA , respectively) decreased and Sensor 4 (2100\AA) increased during this period. The only sensor that has not shown any significant change since launch is the 2800\AA sensor. The gradual increase in output of the 2100\AA sensor appears to be due to a change in bandwidth of the interference filter. A discussion of the long term sensor characteristics will be presented in a later volume.

1.7 The Backscatter Ultraviolet Spectrometer (BUV) Experiment

The BUV experiment continued to perform well during this period. It has been on continuously since activation on orbit 33, and data qualities have been good, with no anomalies observed.

There has been little change in subsystem temperature. Evaluation of the Master Calibration Sequence MCS-D indicates that the mercury strong line value of 2535.3\AA for June has increased to 2535.6\AA for this catalog period. This is well within subsystem requirements which call for a change of no more than $\pm 1\text{\AA}$ from each calibration.

The MCS-A, B and C calibrations are still susceptible to free space radiation, particularly in the area of the South Atlantic Anomaly, as indicated in Volume 1 of the catalog.

The diffuser was deployed without problems every orbit to view the sun, and to view the moon during the gibbous and full moon phases.

The photomultiplier tubes (PMT) have shown a change in gain with time. The degradation has been exponential with time and appears to be leveling off (See Figure 1-17 in Volume 1). Pre-launch calibration data have been presented in Volume 1 (Table 1-3, p. 1-25). In order to evaluate the BUV data, one must multiply the pre-launch calibration data by the ratio of gain-at-launch/gain-at-time-T-after-launch. The PMT gains for the photometer channel and the monochromator channel have averaged 1.11×10^6 and 1.72×10^6 respectively, for this catalog period.

1.8 The Filter Wedge Spectrometer (FWS) Experiment

The FWS chopper motor failed on orbit 815, June 8, 1970 precluding further reception of data. Continued attempts to restart the FWS motor have been unsuccessful. The committee investigating the failure of the chopper motor concluded that: "The most probable cause of failure of the FWS is felt to be due to debris in one or more of the bearings on the slow speed shafts of the reducer or filter wheel."

Before orbit 815, satisfactory data were received from the short wavelength channel, but icing of the bolometer prevented obtaining any usable data from the long wavelength. The committee investigating the degradation of sensory data reported that the probable cause of icing was the condensation of outgassed water vapor on the detector. Also suspected were lubricant from the gear train and adhesive used to hold superinsulation.

1.9 The Selective Chopper Radiometer (SCR) Experiment

The performance of the SCR has been satisfactory for this catalog period. Housekeeping telemetry were nominal with the exception of Channel 1 Calibration Mirror Temperature Monitor, which failed during orbit 905. No operational difficulty has resulted from this failure, since the Channel 1 mirror calibration temperature can be estimated from the Channel 2 mirror calibration temperature which is in the same housing and has been consistently 1°C to 1.5°C lower than the Channel 1 Temperature.

Examination of the calibration data showed consistent variations in space-view levels, which for channels one through five, were associated with radiometer temperature variations. These variations reduced the accuracy of the atmospheric temperature profiles derived from the SCR data. Therefore, new radiometer temperature calibration corrections were established by the experimenter for these channels. Calibration corrections for channel six will be established in the near future. All calibration data and format of the SCR tape will be published in a later volume of the catalog.

1.10 The Interrogation, Recording and Location System (IRLS) Experiment

The IRLS performance during this period was satisfactory. Three new balloons, launched during the first two weeks in July from Ascension Island, were tracked by IRLS during this catalog period as well as six balloons still operating from June launches. No new fixed platforms were interrogated during this period; however, continuing experiments were being performed with those listed in Table 1-2 of Volume 2.

Corrections to Nimbus 4 Data Catalog, Volume 2 — Table 1-3, p. 1-13,
Figures 1-8 and 1-9, pp. 1-16 and 1-17:

For a U.S. Standard Atmosphere 50 mb is equivalent to 20.58 Km and 30 mb is equivalent to 23.85 Km. (From U.S. Standard Atmosphere, 1962, prepared under

sponsorship of the National Aeronautics and Space Administration, the U.S. Air Force and the U.S. Weather Service).

1.11 The Real Time Transmission System (RTTS) Experiment

The Nimbus 4 RTTS is not routinely transmitted because it interferes with the IRIS experiment. Except for initial activation during the early orbits, RTTS has been turned on for only one brief period, from orbit 353 through 356.

Distribution of the Nimbus IV Real Time Transmission System (DRID and DRIR) manual was made prior to launch to all known active APT ground stations. Gridding techniques and grid accuracies described in the manual were checked with actual data after launch. No gridding problems were encountered and grid accuracies were nominal to those listed in the manual.

SECTION 2

ORBITAL ELEMENTS AND DAILY SENSORS "ON" TABLES

The Nimbus 4 Brouwer Mean orbital elements for July and August 1970 are listed in Table 2-1.

The Daily Sensors "On" Table (Table 2-2) lists the times during which the IRIS, IDCS and THIR subsystems were turned on and off. The other subsystems (BUV, MUSE, SCR and SIRS) were on continuously during this catalog period and, therefore, are not individually listed. Data for these subsystems are available for the time spans embraced by IRIS and THIR for any orbit listed.

Orbital sensor coverage in Table 2-2 is divided between daytime (D) and nighttime (N) data. The tabulation includes both the Universal Time (UT) and longitude of orbital equator crossings for the ascending nodes for daytime (D) data and descending nodes for nighttime (N) data. The tape recorder HDRSS (A or B) used to record the data is also listed. If both are used on the same orbit, the one with the longer record time is listed first. The HDRSS with the shortest record time, listed second, represents less than 25 minutes of data. The change from one HDRSS to the other is normally indicated by the short gap of "no data" in the montage displays in Section 3 and 4.

Table 2-2 together with the World Map (Figure 2-1) and the vellum Subsatellite Tracks Overlay attached to the back of this catalog can be used to determine approximate geographic sensor coverages.

A Subsatellite Tracks Overlay is correctly oriented with the World Map when the ascending or descending node line on the overlay lays over the 0 degree latitude (equator) line of the World Map. Orbital sensor coverage is determined by placing an orbit track on the world map at the appropriate ascending node (for daytime) or descending node (for nighttime) longitude for the orbit(s) of interest.

The Subsatellite Tracks Overlay contains 14 correctly spaced tracks which end at the approximate earth day/night transitions. The tracks contain time ticks spaced 5 minutes apart, appropriately annotated at the edge of the overlay, referenced from the Equator. Minutes from equator crossings for all or part of a particular orbit are calculated by adding or subtracting from the ascending or descending node time listed for that orbit in the Daily Sensors "On" Table.

SECTION 3

IMAGE DISSECTOR CAMERA SYSTEM MONTAGES

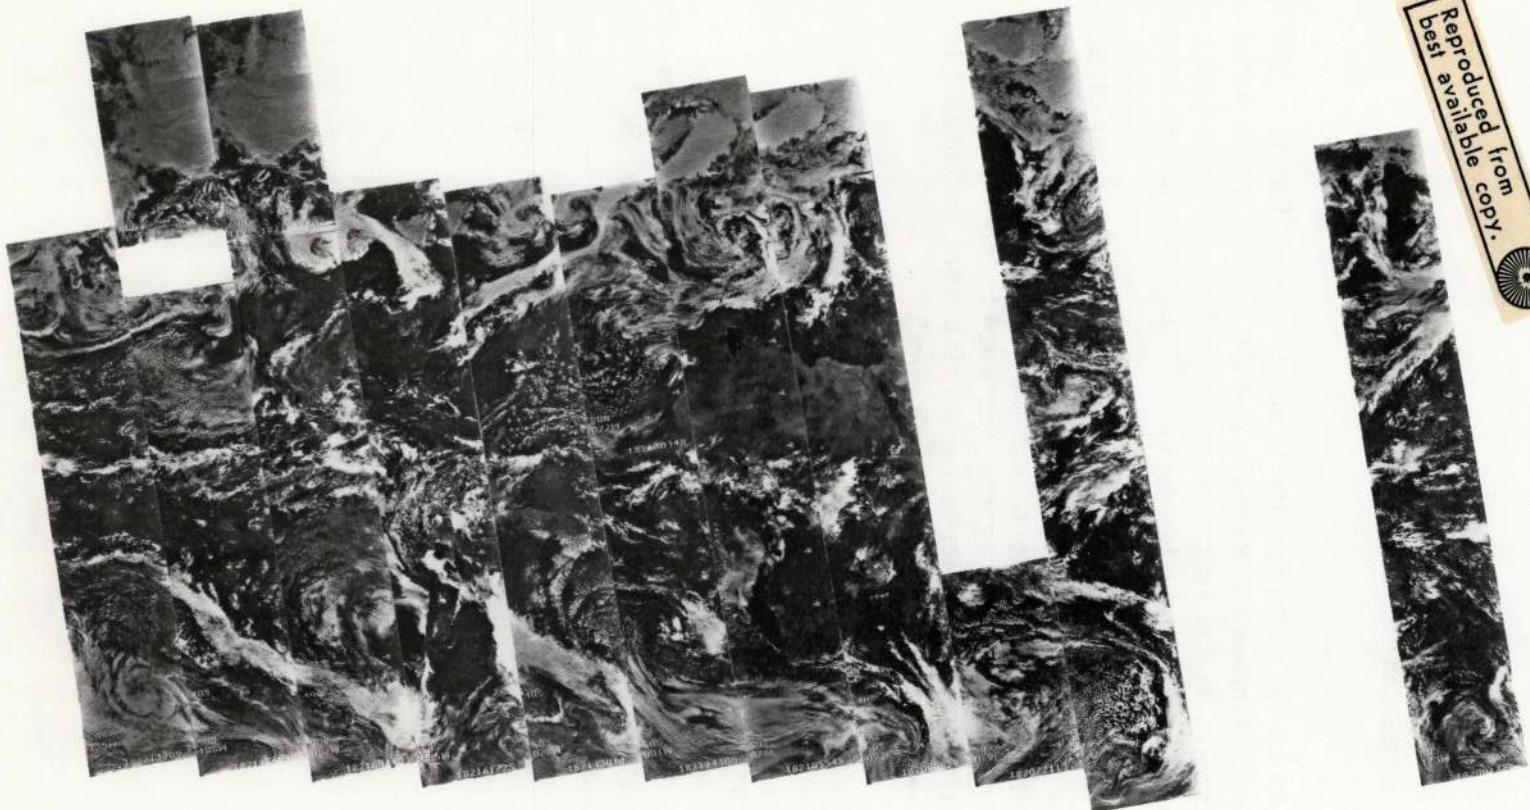

This section depicts the data from the Image Dissector Camera System (IDCS) experiment carried on the Nimbus 4 Meteorological Satellite. The pictorial montage presentation facilitates perusal and search of the IDCS data for preliminary research and also enables the user to determine his specific IDCS film data requirements.

The montages shown represent the daytime television pictures obtained for each day (UT) and are arranged in chronological order in a world montage format. Complete daylight orbital coverage is obtained with 15 consecutive pictures. Successive orbits, displaced about 27 degrees westward in longitude at the equator, provide adjacent pictorial data, with increasing overlap from the equator toward the poles. Data orbit number is indicated below each swath.

A vellum IDCS grid overlay (IDCS Location Guide), attached to the back of this catalog, is to be used for approximate location and orientation of the montage data. Proper alignment of the grid is accomplished by matching the grid indices on the equator with two "T" marks on each montage.

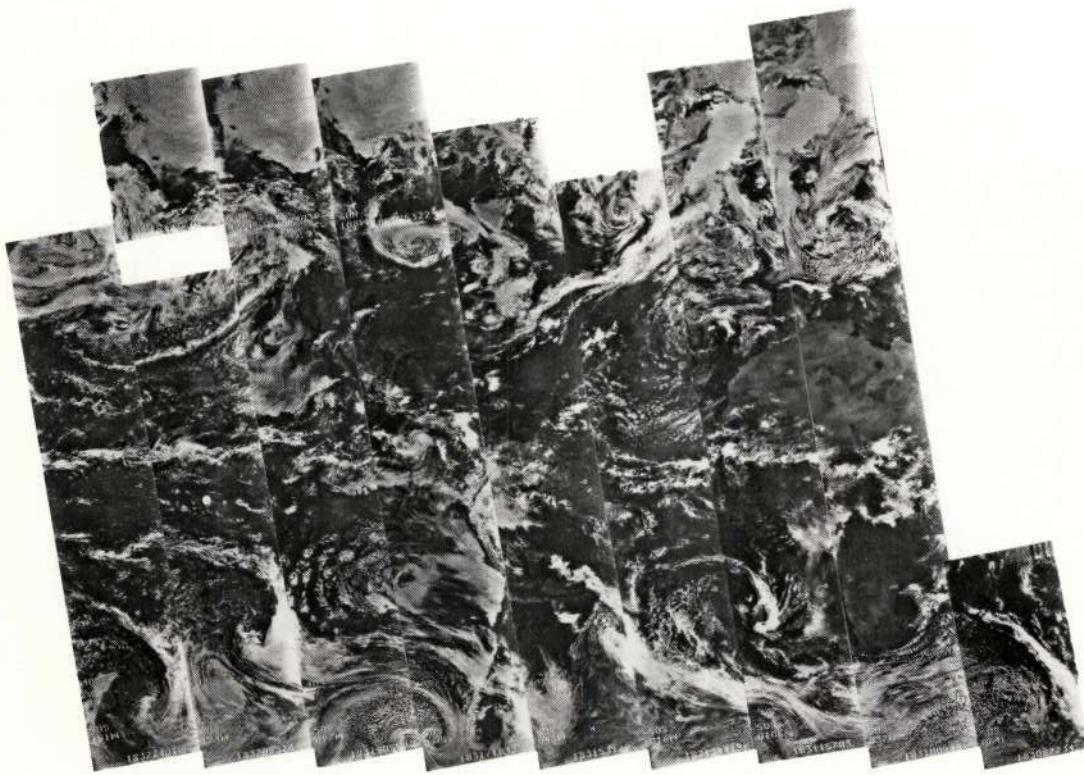

The data area, 5" x 9" in size, has been reduced from the original montage size of 22" x 32". This reduction, required for convenient catalog dimensions, still permits recognition of major cloud and land features.

A description of the IDCS experiment and instructions for ordering IDCS data may be found in the Nimbus IV User's Guide, Section 2.

SECTION 4

TEMPERATURE-HUMIDITY INFRARED RADIOMETER MONTAGES

This section pictorially documents the data from the Temperature-Humidity Infrared Radiometer experiment carried on the Nimbus 4 Meteorological Satellite. The THIR 11.5 and 6.7 micrometer channel montages shown represent the nighttime data (Section 4.1), and the daytime data (Section 4.2), arranged in chronological order. Key latitudes can be read from the superposed grids. Grid points are identified where each swath crosses 60°N, 30°N, EQUATOR, 30°S and 60°S.

Vellum Location Guide overlays, attached to the back of this document, are to be used for general orientation with the data presented in each THIR montage. Proper alignment of the overlay grid is accomplished by matching the grid indices on the equator with the two "T" marks on each montage.

Each THIR montage is provided with a time scale to determine the Universal Time limits required to order processed THIR grid print maps (see p. 57, Nimbus IV User's Guide). The time scale determines the number of minutes from ascending (daytime data) or descending (nighttime data) node time for the interval of data required. To obtain the Universal Time for daytime data, the measured time is to be added to the ascending node time in the northern hemisphere and subtracted in the southern hemisphere. For nighttime data, the measured time is to be subtracted from the descending node time in the northern hemisphere and added in the southern hemisphere. The ascending and descending node times are given in Section 2.

The following alternate procedure also establishes Universal Time limits. Knowing the latitude limits of the study area, the minutes from ascending or descending node can be directly interpolated from Table 4-1. These time values can then be added to or subtracted from node times given in Section 2.

A description of the THIR experiment and instructions for ordering THIR data may be found in the Nimbus IV User's Guide, Section 3.
